In Task 1.2 I have not explained how processes are *deactivated* and *activated* by changes found in signals that lies in their sensitivity list. The same is missing from Figure 1 attached to that task.

In task 2 I have been transferring signals that didn't change (noted by (X)) from the helper-signals to the real signals, effectively creating one extra delta delay at all "stages". I see now that it is not necessary, since there is no active processes.
